10. First-order Logic

Kihong Heo

First-order Logic

- An extension of propositional logic with predicates, functions and quantifiers
- FOL is more expressive than propositional logic
 - Expressive enough to reason about programs
- Not admit completely automated reasoning (i.e., undecidable)

Syntax (1): Terms

- Objects that we are reasoning about
- Terms evaluate to values in an underlying domain (e.g., integers, strings, lists, etc)
 - C.f., All formulae in PL evaluate to true or false
- Basic terms: variables (x, y, z, \dots) and constants (a, b, c, \dots)
- Composite terms: n -ary functions applied to n terms
 - A constant can be viewed as a 0-ary function
- Example:
 - $a, x, f(a), g(x, b), f(g(x, f(b)))$

Syntax (2): Predicates

- Generalization of propositional variables in PL (p, q, r, \dots)
- An n -ary predicate takes n terms as arguments
 - A FOL propositional variable is a 0-ary predicate (P, Q, R, \dots)
- Example:
 - $P, p(f(x), g(x, f(x)))$
 - $isHappy(x), love(x, y), betterThan(x, y)$

Syntax (3): Formula

- Atom: basic elements
 - truth symbols (\perp and \top), n -ary predicates applied to n terms
- Literal: an atom α or its negation $\neg\alpha$
- Formula: literal, the app. of a logical conn. to formulae, or the app. of a quantifier to a formula

$$\begin{array}{lcl} F & \rightarrow & \perp \mid \top \mid p(t_1, \dots, t_n) \\ & & \neg F \\ & & F_1 \wedge F_2 \\ & & F_1 \vee F_2 \\ & & F_1 \rightarrow F_2 \\ & & F_1 \leftrightarrow F_2 \\ & & \exists x.F[x] \\ & & \forall x.F[x] \end{array}$$

Predicates and Functions

- They look similar but different
- Function terms can be nested within each other and inside relation constants
 - E.g., $f(f(x))$, $p(f(x))$
- Predicates cannot be nested within function terms or other predicates
 - E.g., $f(p(x))$, $p(p(x))$

Quantification

quantified
variable

$$\exists x.F[x]$$

$$\forall x.F[x]$$

scope of
quantifier

“ x is bound in $F[x]$ ”

scope of y

$$\forall x.p(f(x), x) \rightarrow (\exists y.p(f(g(x, y)), g(x, y))) \wedge q(x, f(x))$$

scope of x

- A variable is free in $F[x]$ if it is not bound
- $\text{free}(F)$ and $\text{bound}(F)$ denote the free and bound variables of F
- A formula F is closed if F has no free variables
- If $\text{free}(F) = \{x_1, \dots, x_n\}$, the universal closure is $\forall x_1, \dots, x_n.F$ (usually $\forall^* .F$) and its existential closure is $\exists x_1, \dots, x_n.F$ (usually $\exists^* .F$)

Example

- Every dog has its day $\forall x.dog(x) \rightarrow \exists y.day(y) \wedge itsDay(x, y)$
- Some dogs have more days than others $\exists x, y.dog(x) \wedge dog(y) \wedge \#days(x) > \#days(y)$
- The length of one side of a triangle is less than the sum of the lengths of the other two sides
$$\forall x, y, z.triangle(x, y, z) \rightarrow length(x) < length(y) + length(z)$$
- Fermat's Last Theorem
$$\begin{aligned} &\forall n.integer(n) \wedge n > 2 \\ &\rightarrow \forall x, y, z. \\ &\quad integer(x) \wedge integer(y) \wedge integer(z) \wedge x > 0 \wedge y > 0 \wedge z > 0 \\ &\quad \rightarrow x^n + y^n \neq z^n \end{aligned}$$

Interpretation

- A FOL interpretation $I : (D_I, \alpha_I)$ is a pair of a domain and an assignment
 - D_I : a nonempty set of values such as integers, real numbers, etc
 - α_I : a mapping from variables, constants, functions, and predicate symbols to elements, functions, and predicates over D_I
 - Each variable x is assigned to a value from D_I
 - Each n -ary function symbol f is assigned an n -ary function $f_I : D_I^n \rightarrow D_I$
 - Each n -ary predicate symbol p is assigned an n -ary predicate $p_I : D_I^n \rightarrow \{\text{true}, \text{false}\}$

Example

$$F : x + y > z \rightarrow y > z - x$$

- Note: $+$, $-$, $>$ are just symbols and no meaning is given without an interpretation
 - Alternative form: $p(f(x, y), z) \rightarrow p(y, g(z, x))$
- The standard interpretation
 - Domain $D_I = \mathbb{Z}$
 - Assignment $\alpha_I = \{+ \mapsto +_{\mathbb{Z}}, - \mapsto -_{\mathbb{Z}}, > \mapsto >_{\mathbb{Z}}, x \mapsto 13, y \mapsto 42, z \mapsto 1, \dots\}$

Semantics

- Given an interpretation $I : (D_I, \alpha_I)$, $I \models F$ or $I \not\models F$

$$I \models \top$$

$$I \not\models \perp$$

$$I \models p(t_1, \dots, t_n) \quad \text{iff } \alpha_I[p(t_1, \dots, t_n)] = \text{true}$$

$$I \models \neg F \quad \text{iff } I \not\models F$$

$$I \models F_1 \wedge F_2 \quad \text{iff } I \models F_1 \text{ and } I \models F_2$$

$$I \models F_1 \vee F_2 \quad \text{iff } I \models F_1 \text{ or } I \models F_2$$

$$I \models F_1 \rightarrow F_2 \quad \text{iff, if } I \models F_1 \text{ then } I \models F_2$$

$$I \models F_1 \leftrightarrow F_2 \quad \text{iff, if } I \models F_1 \text{ and } I \models F_2, \text{ or if } I \not\models F_1 \text{ and } I \not\models F_2$$

$$I \models \forall x.F \quad \text{iff for all } v \in D_I, I \triangleleft \{x \mapsto v\} \models F$$

$$I \models \exists x.F \quad \text{iff there exists } v \in D_I, I \triangleleft \{x \mapsto v\} \models F$$

where $J : I \triangleleft \{x \mapsto v\}$ denotes an x -variant of I

- $D_J = D_I$

- $\alpha_J[y] = \alpha_I[y]$ for all constant, free variable, function, and predicate symbols y except that $\alpha_J(x) = v$

Example

$$F : \exists x.f(x) = g(x)$$

- Consider the interpretation $I : (D_I, \alpha_I)$
 - $D_I = \{0,1\}$
 - $\alpha_I = \{f(0) \mapsto 0, f(1) \mapsto 1, g(0) \mapsto 1, g(1) \mapsto 0\}$
- Compute the truth value of F under I
 - $I \triangleleft \{x \mapsto v\} \not\models f(x) = g(x)$ for $v \in D_I$
 - $I \not\models \exists x.f(x) = g(x)$ since $v \in D_I$ is arbitrary

Satisfiability and Validity

- A formula F is satisfiable iff there exists an interpretation I such that $I \models F$
- A formula F is valid iff for all interpretations I , $I \models F$
- Satisfiability and validity are dual: F is valid iff $\neg F$ is unsatisfiable
- Satisfiability and validity are defined for closed FOL, but conventionally
 - A formula with free variables is valid : $\forall * .F$ is valid
 - A formula with free variables is satisfiable : $\exists * .F$ is satisfiable

Proof Rules (1)

- According to semantics of negation,

$$\frac{I \models \neg F}{I \not\models F}$$

$$\frac{I \not\models F}{I \models F}$$

- According to semantics of conjunction,

$$\frac{I \models F \wedge G}{I \models F, I \models G}$$

$$\frac{I \not\models F \wedge G}{I \not\models F \mid I \not\models G}$$

Proof Rules (2)

- According to semantics of disjunction,

$$\frac{I \models F \vee G}{I \models F \mid I \models G}$$

$$\frac{I \not\models F \vee G}{I \not\models F, I \not\models G}$$

- According to semantics of implication,

$$\frac{I \models F \rightarrow G}{I \not\models F \mid I \models G}$$

$$\frac{I \not\models F \rightarrow G}{I \models F, I \not\models G}$$

Proof Rules (3)

- According to semantics of iff,

$$\frac{I \models F \leftrightarrow G}{I \models F \wedge G \mid I \models \neg F \wedge \neg G}$$

$$\frac{I \not\models F \leftrightarrow G}{I \models F \wedge \neg G \mid I \models \neg F \wedge G}$$

Proof Rules (4)

- According to the semantics of universal quantification

$$\frac{I \models \forall x.F}{I \triangleleft \{x \mapsto v\} \models F} \text{ for any } v \in D_I$$

- According to the semantics of existential quantification

$$\frac{I \not\models \exists x.F}{I \triangleleft \{x \mapsto v\} \not\models F} \text{ for any } v \in D_I$$

(Usually applied using a domain element v that was introduced earlier in the proof)

Proof Rules (5)

- According to the semantics of universal quantification

$$\frac{I \not\models \forall x.F}{I \triangleleft \{x \mapsto v\} \not\models F} \text{ for a fresh } v \in D_I$$

- According to the semantics of existential quantification

$$\frac{I \models \exists x.F}{I \triangleleft \{x \mapsto v\} \models F} \text{ for a fresh } v \in D_I$$

When applying these rules,
 v must not have been previously used
in the proof

Proof Rules (6)

- A contradiction exists if two variants of the original interpretation ...

$$\frac{J : I \triangleleft \dots \models p(s_1, \dots, s_n) \quad K : I \triangleleft \dots \models p(t_1, \dots, t_n)}{I \models \perp} \text{ for } i \in \{1, \dots, n\}, \alpha_J[s_i] = \alpha_K[t_i]$$

Example (1)

$$F : (\forall x.p(x)) \rightarrow (\forall y.p(y))$$

Example (2)

$$F : (\forall x.p(x)) \rightarrow (\neg\exists y.\neg p(y))$$

Example (3)

$$F : p(a) \rightarrow (\exists x.p(x))$$

Example (4)

$$F : (\forall x.p(x, x)) \rightarrow (\exists x.\forall y.p(x, y))$$

Decidability

- Does there exist an algorithm to solve a problem?
 - Solve: eventually halt and return a correct answer
 - E.g., Halting problem
- Our problem: satisfiability (or dually, validity)
- Satisfiability of PL: decidable
- Satisfiability of FOL: undecidable [Church and Turing]

Summary

- FOL: an extension of PL with predicates, functions and quantifiers
 - Powerful enough to reason about properties of software
- Satisfiability and validity of FOL: undecidable
