Advanced Software Security

10. First-order Logic

Kihong Heo

First-order Logic

- An extension of propositional logic with predicates, functions and quantifiers
- FOL is more expressive than propositional logic
 - Expressive enough to reason about programs
- Not admit completely automated reasoning (i.e., undecidable)

Syntax (1): Terms

- Objects that we are reasoning about
- Terms evaluate to values in an underlying domain (e.g., integers, strings, lists, etc)
 - C.f., All formulae in PL evaluate to true or false
- Basic terms: variables (x, y, z, ...) and constants (a, b, c, ...)
- Composite terms: *n*-ary functions applied to *n* terms
 - A constant can be viewed as a 0-ary function
- Example:
 - a, x, f(a), g(x, b), f(g(x, f(b)))

Syntax (2): Predicates

- Generalization of propositional variables in PL (p, q, r, ...)
- An n-ary predicate takes n terms as arguments
 - A FOL propositional variable is a 0-ary predicate (P, Q, R, ...)
- Example:
 - P, p(f(x), g(x, f(x)))
 - isHappy(x), love(x, y), betterThan(x, y)

Syntax (3): Formula

- Atom: basic elements
 - truth symbols (\perp and \top), n-ary predicates applied to n terms
- Literal: an atom α or its negation $\neg \alpha$
- Formula: literal, the app. of a logical conn. to formulae, or the app. of a quantifier to a formula

$$F \rightarrow \bot | \top | p(t_1, \dots, t_n)$$

$$| \neg F$$

$$| F_1 \wedge F_2$$

$$| F_1 \vee F_2$$

$$| F_1 \rightarrow F_2$$

$$| F_1 \leftrightarrow F_2$$

$$| \exists x. F[x]$$

$$| \forall x. F[x]$$

Predicates and Functions

- They look similar but different
- Function terms can be nested within each other and inside relation constants
 - E.g., f(f(x)), p(f(x))
- Predicates cannot be nested within function terms or other predicates
 - E.g., f(p(x)), p(p(x))

Quantification

- A variable is free in F[x] if it is not bound
- free(F) and bound(F) denote the free and bound variables of F
- A formula F is closed if F has no free variables
- If free $(F) = \{x_1, ..., x_n\}$, the universal closure is $\forall x_1, ..., x_n . F$ (usually $\forall * .F$) and its existential closure is $\exists x_1, ..., x_n . F$ (usually $\exists * .F$)

Example

- Every dog has its day $\forall x.dog(x) \rightarrow \exists y.day(y) \land itsDay(x,y)$
- Some dogs have more days than others $\exists x, y. dog(x) \land dog(y) \land \#days(x) > \#days(y)$
- The length of one side of a triangle is less than the sum of the lengths of the other two sides

$$\forall x, y, z.triangle(x, y, z) \rightarrow length(x) < length(y) + length(z)$$

Fermat's Last Theorem

$$\forall n.integer(n) \land n > 2$$

$$\rightarrow \forall x, y, z.$$

$$integer(x) \land integer(y) \land integer(z) \land x > 0 \land y > 0 \land z > 0$$

$$\rightarrow x^n + y^n \neq z^n$$

Interpretation

- A FOL interpretation $I:(D_I,\alpha_I)$ is a pair of a domain and an assignment
 - D_I : a nonempty set of values such as integers, real numbers, etc
 - α_I : a mapping from variables, constants, functions, and predicate symbols to elements, functions, and predicates over D_I
 - Each variable \boldsymbol{x} is assigned to a value from D_I
 - Each n-ary function symbol f is assigned an n-ary function $f_I:D_I^n o D_I$
 - Each n-ary predicate symbol p is assigned an n-ary predicate $p_I:D_I^n o \{ {
 m true, false} \}$

Example

$$F: x + y > z \rightarrow y > z - x$$

- Note: +, -, > are just symbols and no meaning is given without an interpretation
 - Alternative form: $p(f(x,y),z) \rightarrow p(y,g(z,x))$
- The standard interpretation
 - Domain $D_I = \mathbb{Z}$
 - Assignment $\alpha_I = \{+\mapsto +_{\mathbb{Z}}, -\mapsto -_{\mathbb{Z}}, >\mapsto >_{\mathbb{Z}}, x\mapsto 13, y\mapsto 42, z\mapsto 1, \ldots\}$

Kihong Heo

Semantics

• Given an interpretation $I:(D_I,\alpha_I)$, $I \models F$ or $I \not\models F$

```
\begin{split} I &\models \top \\ I \not\models \bot \\ I &\models p(t_1, \dots, t_n) & \text{iff } \alpha_I[p(t_1, \dots, t_n)] = \text{true} \\ I &\models \neg F & \text{iff } I \not\models F \\ I &\models F_1 \land F_2 & \text{iff } I \models F_1 \text{ and } I \models F_2 \\ I &\models F_1 \lor F_2 & \text{iff } I \models F_1 \text{ or } I \models F_2 \\ I &\models F_1 \to F_2 & \text{iff, if } I \models F_1 \text{ then } I \models F_2 \\ I &\models F_1 \leftrightarrow F_2 & \text{iff, if } I \models F_1 \text{ and } I \models F_2, \text{ or if } I \not\models F_1 \text{ and } I \not\models F_2 \\ I &\models \forall x.F & \text{iff for all } v \in D_I, I \triangleleft \{x \mapsto v\} \models F \\ I &\models \exists x.F & \text{iff there exists } v \in D_I, I \triangleleft \{x \mapsto v\} \models F \end{split}
```

where $J:I \triangleleft \{x \mapsto v\}$ denotes an ${\pmb x}$ -variant of ${\pmb I}$

- $D_I = D_I$
- $\alpha_J[y] = \alpha_I[y]$ for all constant, free variable, function, and predicate symbols y except that $\alpha_J(x) = v$

Example

$$F: \exists x. f(x) = g(x)$$

- Consider the interpretation $I:(D_I,\alpha_I)$
 - $D_I = \{0,1\}$
 - $\alpha_I = \{ f(0) \mapsto 0, f(1) \mapsto 1, g(0) \mapsto 1, g(1) \mapsto 0 \}$
- ullet Compute the truth value of F under I
 - $I \triangleleft \{x \mapsto v\} \not\models f(x) = g(x) \text{ for } v \in D_I$
 - $I \not\models \exists x . f(x) = g(x) \text{ since } v \in D_I \text{ is arbitrary}$

Satisfiability and Validity

- A formula F is satisfiable iff there exists an interpretation I such that $I \models F$
- A formula F is valid iff for all interpretations I, $I \models F$
- Satisfiability and validity are dual: F is valid iff $\neg F$ is unsatisfiable
- Satisfiability and validity are defined for closed FOL, but conventionally
 - A formula with free variables is valid: $\forall * .F$ is valid
 - A formula with free variables is satisfiable : $\exists * .F$ is satisfiable

Proof Rules (1)

According to semantics of negation,

$$\frac{I \models \neg F}{I \not\models F}$$

$$\frac{I \not\models \neg F}{I \models F}$$

According to semantics of conjunction,

$$\frac{I \models F \land G}{I \models F, I \models G}$$

$$\frac{I \not\models F \land G}{I \not\models F \mid I \not\models G}$$

Proof Rules (2)

According to semantics of disjunction,

$$\frac{I \models F \lor G}{I \models F \mid I \models G}$$

$$\frac{I \not\models F \lor G}{I \not\models F, \ I \not\models G}$$

According to semantics of implication,

$$\frac{I \models F \to G}{I \not\models F \mid I \models G}$$

$$\frac{I \not\models F \to G}{I \models F, \ I \not\models G}$$

Proof Rules (3)

According to semantics of iff,

$$\frac{I \models F \leftrightarrow G}{I \models F \land G \mid I \models \neg F \land \neg G}$$

$$\frac{I \models F \leftrightarrow G}{I \models F \land G \mid I \models \neg F \land \neg G} \qquad \qquad \frac{I \not\models F \leftrightarrow G}{I \models F \land \neg G \mid I \models \neg F \land G}$$

Proof Rules (4)

According to the semantics of universal quantification

$$\frac{I \models \forall x.F}{I \triangleleft \{x \mapsto v\} \models F} \text{ for any } v \in D_I$$

According to the semantics of existential quantification

$$\frac{I \not\models \exists x.F}{I \triangleleft \{x \mapsto v\} \not\models F} \text{ for any } v \in D_I$$

(Usually applied using a domain element v that was introduced earlier in the proof)

Proof Rules (5)

According to the semantics of universal quantification

$$\frac{I \not\models \forall x.F}{I \triangleleft \{x \mapsto v\} \not\models F} \text{ for a fresh } v \in D_I$$

According to the semantics of existential quantification

$$\frac{I \models \exists x.F}{I \triangleleft \{x \mapsto v\} \models F} \text{ for a fresh } v \in D_I$$

(When applying these rules, \emph{v} must not have been previously used in the proof)

Proof Rules (6)

A contradiction exists if two variants of the original interpretation ...

$$J: I \triangleleft \dots \models p(s_1, \dots, s_n)$$

$$K: I \triangleleft \dots \models p(t_1, \dots, t_n)$$

$$I \models \bot$$
 for $i \in \{1, \dots, n\}, \alpha_J[s_i] = \alpha_K[t_i]$

Example (1)

$$F: (\forall x.p(x)) \to (\forall y.p(y))$$

Example (2)

$$F: (\forall x.p(x)) \to (\neg \exists y. \neg p(y))$$

Example (3)

$$F: p(a) \to (\exists x.p(x))$$

Example (4)

$$F: (\forall x.p(x,x)) \to (\exists x. \forall y.p(x,y))$$

Decidability

- Does there exists an algorithm to solve a problem?
 - Solve: eventually halt and return a correct answer
 - E.g., Halting problem
- Our problem: satisfiability (or dually, validity)
- Satisfiability of PL: decidable
- Satisfiability of FOL: undecidable [Church and Turing]

Summary

- FOL: an extension of PL with predicates, functions and quantifiers
 - Powerful enough to reason about properties of software
- Satisfiability and validity of FOL: undecidable
